## Case ID: 081010-01

## Accident Narrative

The bus with 48 passengers started the trip at about 19:00 from Khon Kaen. At about midnight the bus was travelling across a mountainous area between Nakhon Ratchasima and Prachinburi (Figure 3-1). On a downhill section between $\mathrm{km} 42+000$ to $\mathrm{km} \mathrm{47+500}$, the driver found a malfunction of the braking system and tried to slow the vehicle down, as reported by the bus staff. At km 44+800, while traveling on a down slope the driver decided to enter an emergency exit ramp in order to stop the bus. The speed of the bus, however, was still considerably high and it failed to stop on the ramp. The bus then went over beyond the emergency ramp and plunged into a deep embankment, crushed to ground and stopped on its right side. In total, 21 persons including the driver were found dead while 17 and 10 persons suffered serious and slight injuries, respectively.

Figure 3-1: Site of the Bus Crash on a Mountainous Road between Nakhon Ratchasima and Prachinburi

From 48 occupants in total, there were 44 university students, one driver and three bus staff. The trip started at 19:00 on 9 September 2008 from Khon Kaen (A). The bus stopped at Tha Pra (B) and Ban Phai (F) at about 19:30. Then, it turned right to Highway No.229, to pick up more passengers at Mancha Khiri (D) and Chonnabot (E) at 22:00 and 22:10, respectively and returned to Bang Phai (F) at about 22:30 to refill the fuel. After all passengers were on board, the bus moved forward to Nakhon Ratchasima (G), and turned left to Highway No. 304 the last stop before approaching the hilly terrain during the night.

Figure 3-2: Bus Route
On the mountainous area between KM.78+00 (M) and 47+500 (N) (kilometer post started from Prachinburi), the bus staff mentioned that the bus could be operated smoothly. He did not find anything unusual during the journey. However, on the critical downhill connecting Thap Lan National Park and Khao Yai National Park starting from KM.47+500, the driver discussed with him that he found some problem while applying the brake. He could not reduce speed as usual. When the bus arrived at KM. $44+800$ (O), the driver decided to approach the 75 m. Emergency Exit Ramp to stop the bus. However, the bus did not stop immediately; instead it kept moving at high speed until reaching the top of the ramp. Then, it suddenly fell into the hillock front first, and stopped on its right side. 21 passengers were killed, while another 17 and 10 suffered serious and slight injuries respectively (Table 3-1).

Table 3-1: Summary of Occupant Injuries

| Vehicle | Fatalities | Serious <br> Injuries | Slight Injuries | No Injury |
| :---: | :---: | :---: | :---: | :---: |
| Bus | 21 | 17 | 10 | - |

## Vehicle Information

The double deck bus was a rental bus or non fixed route bus. The last vehicle registering was updated on 26 June 2007. The 8 cylinder Hino engine operated with a maximum of 320 hp . There were 3 axles and 8 wheels. The curb weight was $16,600 \mathrm{~kg}$, and $2.4 \times 12.0 \mathrm{x}$ 4.2 m in width, length, and height.

A lower deck arranged into 5 parts including the driver cab, staff room, occupants compartment, luggage room and engine box. In the occupants compartment, a u-shape bench was installed with a table in the middle, close to another three sets of passenger seats at the end. On the upper deck, the seating configuration of the bus was arranged with 18 sets, ten on the right and eight on the left. There was a stair case between the fifth and the sixth row on the left. Each set connected between two seats except for the five seats on the last row. The passenger's seats were all individual but attached tightly as a pair. The seats were connected to the bus body by a pair of steel hooks, one attached to the floor while another one was attached to a side bar (Figure 3-3). However, only the last row and three sets on the lower deck the seats were installed on the bus floor by connected (connecting?) bolts. No seatbelt was installed on the seats.

Figure 3-3: Seating Configuration
The suspension and brake system were inspected by a local bus mechanic and the forensic police on the day of the crash. The findings are summarized as follows,

1. Brake pads were in good condition. The spaces between pad and wheel were normal. Only at the middle axle the space was bigger than the other wheels, about 2 mm (Figure 3-4).
2. Steering rod was damaged due to the crash.
3. The driving gear was in the 3rd position.
4. Before this trip, two sets of air suspension were replaced.

Figure 3-4: Suspension and Brake System
The bus was deformed entirely on the front part due to the impact with a hillock. The driver compartment starting from the A-pillar intruded into the bus staff room and occupants
compartment. The driver and passengers' doors and console were crushed. The front axle was also bent. However, the damage on the roof as seen on the photo occurred during the post crash evacuation.

Figure 3-5: Frontal Deformation

Figure 3-6: Damaged Bus

Right Side

Figure 3-7: Side Dimension

Figure 3-8: Top View Dimension

Due to major damage to the front part, the intrusion extended to the occupants compartment on the upper deck. The first and second pillars were displaced while all of the passenger seats were separated from their original position. Figure 3-9 presents the comparison before and after the crash. Figure 3-10 and Figure $3-11$ show the seating dimension and the hook connecting the seats and the bus body as mentioned.

Figure 3-9: Seating Configuration Before and After Crash

Figure 3-10: Seating Dimension

Figure 3-11: Seating Connection
Three seats on the lower deck (Seat No.42-47) were installed to the floor with connecting bolts. There was only one set in place, while the other two were missing. Figure 3-12 shows that the bolts were still firmly screwed to the steel structure.

Figure 3-12: Lower Deck Seat

## Driver Information

The driver was a 43 year old male. He was a native of Pichit but lived in Khon Kaen. Back in 1987, he was granted a Driver License Class II, license to drive cargo trucks or buses carrying less than 20-passenger, with more than $3,500 \mathrm{~kg}$ total in weight. The existing license has been validated for the period from 16 May 2007 until 15 May 2010.
, The driver started his carrier in the bus industry when he was young. He worked at Mo Chit, National bus station in Bangkok as a bus staff for number of years. After that, he became a driver for fixed routes and non-fixed routes and gathered over 20 years of experience according to his wife and co-workers. Before taking this trip, he had traveled to Southern provinces for military army reciprocation and returned to Khon Kaen on 8 October 2008.

The day before the trip, the driver and his staff repaired the air suspensions of the bus. They changed two out of four. His staff started driving the bus at the beginning of the trip, and they switched again after arriving in Ban Phai, about half an hour later. Figure 3-13 shows the timeline of driving hours before the crash.

19:00 22:30 00:00 03:00
Figure 3-13: Driving Hour

## Highway Information

Highway No. 304 serves as a main Northeastern-Eastern corridor. The total length, from Nakhon Ratchasima to Chachoengsao, is about 242 km . It passes through the mountainous area connecting Wang Nam Khieo (Nakhon Ratchasima) and Nadi (Prachinburi).

In the mountainous area of the crash, there was a two lane undivided, asphaltic concrete road. The road is between Thap Lan National Park and Khao Yai National Park. The downhill section starts from KM.47+500 with approximately 6\% grade. At KM.44+800, where the crash occurred, it composes of a 242.837 m . radius curve with a total length of 124.682 m . In addition, at the starting point of the curve, an emergency exit ramp is constructed with a 75 m . long embankment and a $6.7 \%$ uphill grade.

Figure 3-14: Road and Environment at the crash scene
The sight distance during nighttime is limited by the lack of a road lighting system. Nevertheless, delineators are installed along the traveling way on the guiding posts, barriers or signs in order to increase the visibility during darkness (Figure 3-15).

Figure 3-15: Driver's View on the Emergency Exit Ramp
The traffic control devices installed before approaching the crash location are summarized as follow;

$500 \mathrm{~m} \quad$| "Emergency Exit 500 m Ahead" Warning Sign |  |
| :--- | :--- |
| 300 m | "Downhill" and "Use Low Gear" Warning Sign <br> "Hazardous Curve Ahead, High Crashes Location" Warning Sign <br>  <br>  <br> Emergency Exit Warning Sign |
| Right Curve Warning Sign |  |
| 200 m | Blinking Amber Lighting |
| "Emergency Exit 200 m Ahead" Warning Sign |  |

## Crash Statistic

The 11 years crash statistic (1997-2007) of Highway No. 304 between KM.78+000 and $42+000$ is shown in Table 3-2. There were 470 crashes in total, with 169 fatalities and 979 injuries. Single vehicle crashes shared about $60 \%$ of the total crashes while another $40 \%$ were multiple vehicle crashes. In addition, considering only single vehicle crashes, there were up to 588 trucks or $81 \%$, involved in the crashes.

Table 3-2: 11 Years Crash Statistic on Highway No. 304 (km.78+000 to km.42+000)

| Crashes | $\mathbf{4 7 0}$ |
| :--- | :--- |

Focusing more specifically on the downhill section between KM.47+500 and KM.42+000, the proportion of crashes on this 5.5 km section covered more than $70 \%$ of the total mountainous section. The trucks represent the highest share of vehicle types involved in
crashes (84\%) as shown in Table 3-3. Table 3-4 lists a high record of victims of crashes along this mountainous section.

## Physical Evidence

After examining the crash scene starting from the previous curve to the crash scene, no distinct marks showing the bus movement, evasive maneuver or tire marks, prior to approaching the emergency exit were found. The condition of the ramp, however, was modified during the time the TARC team performed its investigation. Therefore, some information of the ramp relied on the photos from local news reporters. As clearly seen from Figure 3-16, there were no sliding wheel tracks printed on the ramp, even between the wheels and grass nearby.

Figure 3-16: Ramp Condition after Crash
Courtesy of Mr. Pairoj Kled-ngoen
After the bus reached the top of the hill, it suddenly fell into a $24 \%$ downhill hillock and hit the embankment with its front, considered as Point of Impact (POI). The bus overturned and kept moving for some distance and stopped on its left side (Figure 3-17). The total distance the bus moved from the top to POR was about 40 m . (inclined distance) as shown in the moving diagram in Figure 3-18.

## Injuries Information

There were 21 fatalities, 17 serious injuries and 10 slight injuries reported from this crash. Figure $3-19$ shows the diagram of seating position of the occupants by severities. The red shows fatalities, orange the serious injuries and yellow the slight injuries. Unspecified occupants are shown in blue. The detail of injuries information is shown in Table 3-5.

## Accident Contributing Factors

## Brake System on Downhill

Driving on a long distance of mountainous section requires high skills of driving maneuver, especially for heavy vehicles which are equipped with an air brake system. Generally, the mechanism of air brake system starts by taking filtered air from the atmosphere, compressing it, and keeping it in high-pressure reservoirs. When applying the brakes, this high pressure air is routed to the operating cylinders on the brakes, which actuate the braking hardware and slow the vehicle (Wikipedia, 2009). The air brake system used for heavy vehicles is separated into two parts, the supply system and the control system. While the engine is working, the compressed air is routed through the air compressor system and stored in the reservoir. When the driver presses on the brake pedal, the supply line from the trailer brake circuit receives air from the air tank. However, when applying the brakes more frequently, it is possible that the engine could not supply the compressed air into the tank as it used to and cause a shortage of air in the system. In this case, the bus traveled on the hilly section for about 30 km before the bus driver found the error in the brake system while on the downhill section. The driver controlled the bus using the lowest possible gear. The mechanical inspection showed that the driving gear was in the third position. Accordingly, all of braking pads were in good condition without burns from the scratching with the rotating wheels.

There is a possibility of air leaking. However, if detected by the valves, the entire supply system will be shut down automatically. The post investigation could not determine whether this former scenario took place since most of the system was destroyed in the crash.

In addition, there were no reports blaming the awareness of the driver. He was not found drowsy, under the influence of drug or alcohol or inattentive according to passengers and staff statements.

## Emergency Exit

A speed-distance calculation was performed to determine the ability of the emergency ramp to reduce the speed. Fixing a coefficient of friction equal 0.6 on $6.7 \%$ grade uphill as measured from the scene; the speed drops only by $9-10 \mathrm{~km} / \mathrm{hr}$ if entering a speed between $51-58 \mathrm{~km} / \mathrm{hr}$. The efficiency of the ramp is possibly reduced by the natural compaction of the gravel pavement over time. It was revealed from relevant agencies that this exit has been improved the roughness condition monthly. However, the soil was easily compacted again after pouring of the falling rain.

## Seating Strengthening and Occupants Restraint System

People bouncing on each other and the seats detaching from their position caused harm to the occupants during the event of crash, according to victims statements. The crash consequences were reminiscent of another bus crash which happened on Highway No. 304 in Doi Saket, Chiang Mai, where 17 passengers died. At that time, the seating on the upper deck detached from the body, as in this crash. It was documented that the fixing system was almost the same, where the hook fixed the seat on the bus body near the walkway, while another set of bolts was fixed into the sidebar. However, in Chiang Mai, the bus overturned more than 720 degrees, while the bus turned 90 degree after frontal impact in this crash. It was revealed from the bus manufacturer that this installation is preferred by the bus companies since it requires less time and power to rearrange the seating configuration compared to fixing the seat on the bus floor. This issue is still not addressed in the Land Traffic Act or Land Transport Act.

Figure 3-20: Detached Seats of the 19 January 2007 Bus Crash

Figure 3-21: Detached Seats of the 10 October 2008 Bus Crash
